

ONE UPPER ESTIMATE ON THE NUMBER OF LIMIT CYCLES OF EVEN DEGREE LIÉNARD EQUATIONS IN THE FOCUS CASE

GRISHA KOLUTSKY

ABSTRACT. We give an explicit upper bound for a number of limit cycles of the Liénard equation $\dot{x} = y - F(x)$, $\dot{y} = -x$ of even degree in the case its unique singular point $(0, 0)$ is a focus.

M. Caubergh and F. Dumortier get an explicit linear upper estimate for the number of large amplitude limit cycles of such equations [CD]. We estimate the number of mid amplitude limit cycles of Liénard equations using the Growth-and-Zeros theorem proved by Ilyashenko and Yakovenko [IYa].

Our estimate depends on four parameters: n , C , a_1 , R . Let $F(x) = x^n + \sum_{i=1}^{n-1} a_i x^i$, where $n = 2l$ is the even degree of the monic polynomial F without a constant term, $\forall i \ |a_i| < C$, so C is the size of a compact subset in the space of parameters, R is the size of the neighborhood of the origin, such that there are no bigger than l limit cycles located outside of this neighborhood, $|a_1|$ stands the distance from the equation linearization to the center case in the space of parameters and $2 - |a_1|$ stands the distance from the equation linearization to the node case in the space of parameters.

Key words and phrases. Limit cycles, Poincaré map, Liénard equations, Hilbert's 16th problem, Hilbert-Smale problem.

1. HILBERT-SMALE PROBLEM

In 1977 A. Lins Neto, W. de Melo and C. C. Pugh [LMP] examined small perturbations of a linear center for a special class of polynomial vector fields on the plane. This class is called Liénard equations:

$$\begin{cases} \dot{x} = y - F(x), \\ \dot{y} = -x, \end{cases} \quad (1)$$

where F is a polynomial of odd degree. Actually, Liénard in 1928 introduced it for a modeling of the non-linear damping in electric circuits [L]. It was a generalization of the famous Van der Pol equation [V].

Authors of [LMP] proved the finiteness of limit cycles for a Liénard equation of odd degree n . Let us remind that the Finiteness problem (also known as the "Dulac problem") was solved in full generality only in 1991 by Ilyashenko [I1] and in 1992 by Écalle [E] independently.

Also A. Lins Neto, W. de Melo and C. C. Pugh [LMP] conjectured that the number of limit cycles of (1) is not bigger than $\frac{n-1}{2}$.

In 1998 S. Smale [S] suggested to consider a restriction of the second part of the Hilbert's 16th problem to Liénard equations of odd degree. He conjectured that there exists an integer n and real C such that the number of limit cycles of (1) is not bigger than Cn^q .

In 1999 Yu. Ilyashenko and A. Panov [IP] got an explicit upper bound for the number of limit cycles of Liénard equations through the (odd) degree of the monic polynomial F and magnitudes of its coefficients. Their result reclined on the theorem of Ilyashenko and Yakovenko that binds the number of zeros and the growth of a holomorphic function [IYa].

In 2007 F. Dumortier, D. Panazzolo and R. Roussarie [DPR] constructed a counterexample to the conjecture of A. Lins Neto, W. de Melo and C. C. Pugh. Namely, they presented an example of a Liénard equation of odd degree n with at least $\frac{n+1}{2}$ limit cycles.

In 2008 Yu. Ilyashenko [I3] suggested to prove a result analogous to the one of Ilyashenko and Panov for Liénard equations of even degree.

In 2008 M. Caubergh and F. Dumortier in [CD] proved the following theorem for Liénard equations of even degree.

Theorem 1. *Let K be a compact set of polynomials of degree exactly $n = 2l$, then there exists $R > 0$ such that any system having an expression (1) with $F \in K$ has at most l limit cycles having an intersection with $\mathbb{R}^2 \setminus B_R$.*

Here and bellow B_R denotes the ball around the origin with the radius R .

2. NOTATIONS AND THE ILYASHENKO STRATEGY

From now on we will consider a system (1), where F is a monic polynomial of even degree $n = 2l$ without a constant term.

Remark 1. *The assumption $F(0) = 0$ does not reduce the generality; it may be fulfilled by a shift $y \mapsto y + a$. The assumption that F is monic may be fulfilled by rescaling in x , y and reversing the time if necessary.*

Let v be an analytic vector field in the real plane, that may be extended to $\mathbb{C}^2$. For any set D in a metric space denote by $U^\varepsilon(D)$ the ε -neighborhood of D . The metrics in $\mathbb{C}$ and $\mathbb{C}^2$ are given by:

$$\begin{aligned}\rho(z, w) &= |z - w|, & z, w \in \mathbb{C}; \\ \rho(z, w) &= \max(|z_1 - w_1|, |z_2 - w_2|), & z, w \in \mathbb{C}^2.\end{aligned}$$

Denote by $|D|$ the length of the segment D . For any larger segment $D' \supset D$, let $\rho(D, \partial D')$ be the Hausdorff distance between D and $\partial D'$.

We want to apply the next theorem proved by Ilyashenko and Panov [IP]. In fact, it is the easy corollary from the Growth-and-Zeros theorem for holomorphic functions proved by Ilyashenko and Yakovenko [IYa].

Consider the system

$$\dot{x} = v(x), \quad x \in \mathbb{R}^2. \quad (2)$$

Theorem 2. *Let Γ be a cross-section of the vector field v , $D \subset \Gamma$ a segment. Let P be the Poincaré map of (2) defined on D , and $D \subset D' = P(D)$. Suppose that P may be analytically extended to $U = U^\varepsilon(D) \subset \mathbb{C}$, $\varepsilon < 1$, and $P(U) \subset U^1(D') \subset \mathbb{C}$. Then the number $\#LC(D)$ of limit cycles that cross D admits an upper estimate:*

$$\#LC(D) \leq e^{2|D|\varepsilon^{-1}} \log \frac{|D'| + 2}{\rho(D, \partial D')}. \quad (3)$$

The same is true for P replaced by P^{-1} .

Actually, the *Ilyashenko strategy* is the application of the previous theorem. It requires a purely qualitative investigation of a vector field, i.e. a construction of such D for every nest of limit cycles. This strategy was applied before in papers [I2] and [IP].

We take K from the Theorem 1 to be the space of monic polynomials of degree exactly n with coefficients, which absolute values are bounded by some positive constant $C \geq 4$, i.e.

$$F(x) = x^n + \sum_{i=1}^{n-1} a_i x^i, \quad \forall i : |a_i| < C.$$

If $0 < |a_1| < 2$ then the unique singular point $(0, 0)$ of the system (1) is a focus. In our work we will consider only this case.

3. BENDIXSON TRAP FROM WITHIN

In this Section we construct an interval D , which lies inside B_R and intersects transversally all limit cycles in B_R . Also we find an upper estimate for the *Bernstein index*, $b = \log \frac{|D'| + 2}{\rho(D, \partial D')}$. To do that we need

to estimate $\rho(D, \partial D')$ from below, where $D' = P(D) \subset D$ and P is the Poincaré map defined on D (see the Figure 1).

FIGURE 1. The inverse Poincaré map of the Liénard equation (1) inside the ball B_R .

Let φ, r be polar coordinates on $\mathbb{R}^2$, $\dot{\varphi}, \dot{r}$ be derivatives with respect to (1).

First of all we need to determine the size of the domain, where the Poincaré map is defined.

Lemma 1. Put $\sigma = \frac{|a_1|(2-|a_1|)}{8C} e^{\frac{8\pi}{|a_1|-2}}$. In the focus case ($0 < |a_1| < 2$) the Poincaré map for the system (1) is well defined in B_σ .

Proof. Let us calculate $\dot{r}$.

$$\begin{aligned} \dot{r} &= \frac{x\dot{x} + y\dot{y}}{r} = \frac{r \cos \varphi (r \sin \varphi - F(r \cos \varphi)) - r^2 \sin \varphi \cos \varphi}{r} = \\ &= -\cos \varphi F(r \cos \varphi) = -r \cos^2 \varphi \sum_{i=1}^n a_i (r \cos \varphi)^{i-1} = \\ &= -r \cos^2 \varphi (a_1 + O(r, \varphi)), \quad (4) \end{aligned}$$

where $O(r, \varphi) = \sum_{i=2}^n a_i (r \cos \varphi)^{i-1}$.

Let us calculate $\dot{\varphi}$.

$$\begin{aligned} \dot{\varphi} &= \frac{x\dot{y} - y\dot{x}}{r^2} = \frac{-r^2 \cos \varphi - r^2 \sin^2 \varphi + r \sin \varphi F(r \cos \varphi)}{r^2} = \\ &= -1 + \frac{\sin \varphi F(r \cos \varphi)}{r} = -1 + \sin 2\varphi \left(\frac{a_1}{2} + \frac{O(r, \varphi)}{2} \right). \quad (5) \end{aligned}$$

The absolute value of the function $O(r, \varphi)$ admits the following upper estimate in $B_{\frac{1}{2}}$:

$$|O(r, \varphi)| \leq \sum_{i=2}^n Cr^{i-1} = Cr \frac{1-r^{n-1}}{1-r} < \frac{Cr}{1-r} \leq 2Cr. \quad (6)$$

Therefore, in $B_{\frac{2-|a_1|}{4C}} \subset B_{\frac{1}{2}}$: $\dot{\varphi} \leq \frac{|a_1|-2}{4}$. Indeed,

$$\begin{aligned} \dot{\varphi} &\leq -1 + |\sin 2\varphi| \left(\frac{|a_1|}{2} + \frac{|O(r, \varphi)|}{2} \right) \leq -1 + \frac{|a_1|}{2} + Cr \leq \\ &\leq \frac{|a_1|-2}{2} + C \frac{2-|a_1|}{4C} = \frac{|a_1|-2}{4}. \end{aligned}$$

Also, in $B_{\frac{2-|a_1|}{4C}}$: $|\dot{r}| \leq 2r$. Indeed,

$$\begin{aligned} |\dot{r}| &\leq |r \cos^2 \varphi| (|a_1| + |O(r, \varphi)|) \leq (|a_1| + 2Cr) r \leq \\ &\leq \left(|a_1| + 2C \frac{2-|a_1|}{4C} \right) r \leq \frac{2+|a_1|}{2} r \leq 2r. \end{aligned}$$

Hence, any trajectory starting from any point from B_σ rotates around the origin on the angle not less than 2π before leaving $B_{\frac{2-|a_1|}{4C}}$.

Indeed, $\dot{\varphi} \leq \frac{|a_1|-2}{4}$ implies that during the time, $\Delta t = 2\pi \frac{4}{2-|a_1|}$ the variation of the angle, $\Delta \varphi \geq 2\pi$ and the variation of the radius, $\Delta r \leq e^{2\frac{4\pi}{2-|a_1|}}$ during the same time Δt , because $|\dot{r}| \leq 2r$.

Finally, $\sigma e^{\frac{8\pi}{2-|a_1|}} = \frac{|a_1|(2-|a_1|)}{8C} \leq \frac{2-|a_1|}{4C}$. $\square$

Let us denote by Y the maximal y -coordinate of the point of intersection between the most external limit cycle which lies inside B_R (if it exists, of course) and y -axis.

Lemma 2. *If a_1 is negative, then $\dot{r} > 0$ in B_σ . Let $D = [\sigma, Y] \subset 0y$. Then $d = \rho(D, \partial D') \geq \frac{\pi|a_1|}{2}\sigma$.*

Proof. If $r < \sigma$, then $r < \frac{1}{2}$ and by (6): $|O(r, \varphi)| \leq 2Cr < \frac{|a_1|}{2}$.

Therefore by (4),

$$\dot{r} > r \cos^2 \varphi \left(-a_1 - \frac{|a_1|}{2} \right) = -\frac{a_1}{2} r \cos^2 \varphi > 0.$$

This proves the first part of the Lemma.

Consider the orbit γ of the system (1) that passes through the point $(0, \sigma)$. Then the Hausdorff distance, d can be estimated as follows:

$$d \geq \left| \int_0^{2\pi} \dot{r}(\gamma) d\varphi \right| > \int_0^{2\pi} -\frac{a_1}{2} \sigma \cos^2 \varphi d\varphi = \frac{\pi|a_1|}{2} \sigma.$$

This inequality completes the proof of the Lemma. $\square$

Remark 2. *For positive a_1 we can get the same results just by reversing of the time.*

Now we can estimate b from above:

$$b \leq \log \frac{R+2}{d} \leq \log \frac{2(R+2)}{\pi|a_1|\sigma} < \frac{R+2}{|a_1|\sigma}. \quad (7)$$

4. COMPLEX DOMAIN OF THE INVERSE POINCARÉ MAP

The Theorem 2 uses the width ε of the complex domain $U^\varepsilon(D)$ to which the (inverse) Poincaré map may be extended. We will apply the following theorem to estimate this ε from below.

Theorem 3. *Let $P : D \rightarrow D'$ be the Poincaré map of (2). For any $x \in D$ denote by $\varphi_{x,P(x)}$ the arc of the phase curve of (2) starting at x and ending at $P(x)$.*

Let

$$\Omega(D) = \bigcup_{x \in D} \varphi_{x,P(x)},$$

and

$$1 \leq \mu = \max_{U^2(\Omega)} |v|, \quad L = 2\mu. \quad (8)$$

Let $t(x)$ be the time length of the arc $\varphi_{x,P(x)}$, and

$$T_{\max} = \max_{x \in D} t(x), \quad T = T_{\max} + 1.$$

Let

$$\delta \leq e^{-LT}, \quad \lambda = \sqrt{\delta}, \quad \varepsilon = \delta^2. \quad (9)$$

Suppose that (z_1, z_2) are coordinates in $\mathbb{C}^2$, ${}^{\mathbb{C}}\Gamma = \{z_1 = 0\}$, $v = (v_1, v_2)$.

Let $\Pi_\delta = U^\delta(0) \times U^\lambda(D') \subset \mathbb{C}^2$. Suppose that

$$\left| \frac{v_2}{v_1} \right| \leq \mu \quad \text{in} \quad \Pi_\delta. \quad (10)$$

Then the Poincaré map $P : D \rightarrow D'$ of (2) may be analytically extended to $U^\varepsilon(D) \subset {}^{\mathbb{C}}\Gamma$, and $P(U^\varepsilon(D)) \subset U^1(D)$.

The same is true for P replaced by P^{-1} . In this case $P^{-1}(D) = D'$, $\Omega(D) = \bigcup_{x \in D'} \varphi_{x,P(x)}$.

For the proof see [IP]. □

Bellow we will produce some preliminary calculations, which would allow us to apply the Theorem 3 later.

Definition 1. A C -monic polynomial is a real polynomial in one variable with the highest coefficient one and other coefficients no greater than C in absolute value, with zero constant term.

Proposition 1 (Properties of C -monic polynomials). *Let F be a C -monic polynomial of degree n , $C \geq 2$. Then*

$$\max_{x \in [0, X]} |F(x)| \leq 2X^n \quad \text{for } X \geq C + 1, \quad (11)$$

$$\max_{x \in [0, X]} |F'(x)| \leq Cn^2 X^{n-1} \quad \text{for } X \geq 1, \quad (12)$$

$$|F(z)| \leq 2C|z| \quad \text{for } z \in \mathbb{C}, |z| \leq \frac{1}{2}. \quad (13)$$

For the proof see [IP]. $\square$

Lemma 3. *Let v be the vector field given by the system (1). Then μ and L from the Theorem 3 admits the following estimates:*

$$\mu \leq 3(R + 2)^n \quad L \leq 6(R + 2)^n. \quad (14)$$

Proof. By definition, $U^2(\Omega) \subset B_{R+2}$. So

$$|v| \leq |\dot{x}| + |\dot{y}| \leq |x| + |y| + |F(x)| \leq 2(R + 2) + 2(R + 2)^n,$$

where the last inequality provided by (11). Hence,

$$\mu \leq 2(R + 2 + (R + 2)^n) \leq 3(R + 2)^n, \quad L = 2\mu \leq 6(R + 2)^n,$$

that proves the Lemma. $\square$

Let $G = B_R \setminus B_\sigma$. Then $\Omega = \bigcup_{x \in D} \varphi_{x, P(x)} \subset G$.

Lemma 4. *Let γ_y be the arc $\varphi_{y, P^{-1}(y)}$ of the phase curve of (1), where $y \in D$. Then $t(y)$, the time length of γ_y , admits an estimate*

$$T_{\max} = \max_{y \in D} t(y) \leq \frac{25C^2 n^2 R^n}{\sigma}. \quad (15)$$

Proof. The arcs γ_y , $y \in D$ belongs to G . We will split G into two domains: $|\dot{x}| \leq \alpha$ and $|\dot{x}| > \alpha$ for α small to be chosen later. The second domain contains two parts of γ_y : one with $\dot{x} < -\alpha$, the other with $\dot{x} > \alpha$. The time length of any of them is no greater than $\frac{2R}{\alpha}$. In the next Proposition we will choose α so small that the curvilinear strip

$$S_\alpha = \{(x, y) \in G : |y - F(x)| \leq \alpha\}$$

is crossed by the orbits of (1) in the time no greater than 1.

Proposition 2. *Let*

$$\omega = \frac{\sigma}{3C}, \quad \alpha = \frac{\omega}{2Cn^2 R^{n-1}} = \frac{\sigma}{6C^2 n^2 R^{n-1}}. \quad (16)$$

Then the time length of any arc of the orbit of (1) located in S_α is no greater than 1.

Proof. By the symmetry arguments it is sufficient to prove that in $S_\alpha^+ = S_\alpha \cap \{x > 0\}$:

$$\frac{d}{dt}(y - F(x)) \leq -2\alpha.$$

Let us first prove that in S_α we have: $|x| > \omega$. Namely, let $|x| \leq \omega$, $|y - F(x)| \leq \alpha$. Then $(x, y) \in D_\sigma$. Indeed,

$$|x| + |y| \leq \omega + \alpha + \max_{[0, \omega]} |F(x)|.$$

By (16), $\alpha < \omega < \frac{1}{2}$. By (13), $|F(x)| \leq 2C\omega$. Hence, for $x \in [0, \omega]$,

$$|x| + |y| \leq (2C + 2)\omega < 3C\omega = \sigma.$$

By (12), $|F'(x)| \leq Cn^2R^{n-1}$ in G . Therefore, for x such that $(x, y) \in S_\alpha^+$ we have: $x > \omega$, and

$$\frac{d}{dt}(y - F(x)) = -x - F'(x)(y - F(x)) \leq -\omega + \alpha Cn^2R^{n-1} < -2\alpha,$$

because $\alpha = \frac{\omega}{2Cn^2R^{n-1}} < \frac{\omega}{2Cn^2R^{n-1} + 2}$. $\square$

Let us finish the proof of the Lemma 4.

The arc γ_y spends in S_α no longer time than 2 (two crossings, each one no longer in time than 1, by the previous Proposition); in $G \setminus S_\alpha$ no longer time than $\frac{4R}{\alpha}$ (two crossings, one to the left, another to the right with $|\dot{x}| \geq \alpha$). Hence,

$$T_{\max} \leq 2 + \frac{4R \cdot 6C^2n^2R^{n-1}}{\sigma} < \frac{25C^2n^2R^n}{\sigma}.$$

This calculation completes the proof of the Lemma 4. $\square$

Remark 3. The same inequality holds for $T_{\max}$ replaced by $T_{\max} + 1$.

Let us check the last assumption of the Theorem 3.

Lemma 5. Take

$$\varepsilon = \exp\left(-\frac{300C^2n^2R^n(R+2)^n}{\sigma}\right), \quad \delta = \sqrt{\varepsilon}, \quad \lambda = \sqrt{\delta}. \quad (17)$$

Let, as in the Theorem 3, $\Pi_\delta = U^\delta(0) \times U^\lambda(D') \subset \mathbb{C}^2$. Then in Π_δ :

$$\left|\frac{v_2}{v_1}\right| < \mu.$$

Proof. By (13) and by definition of Π_δ ,

$$|v_1(z)| \geq ||z_1| - F(z)| \geq (\sigma - \lambda) - 2C\delta > \delta,$$

where the last inequality is trivial. On the other hand, $v_2 = -x$. In Π_δ , $|v_2| \leq \delta$. Hence, $\left|\frac{v_2}{v_1}\right| < 1 < \mu$. $\square$

Lemma 6. *The inverse Poincaré map of the Liénard equation (1) may be extended to the domain $U^\varepsilon(D) \subset \mathbb{C}$, where $\varepsilon = e^{-\frac{300C^2n^2R^n(R+2)^n}{\sigma}}$. Moreover, $P^{-1}(U^\varepsilon(D)) \subset U^1(D')$.*

Proof. This Lemma following from the Theorem 3. Lemmas 3 and 5 verifies assumptions 8 and 10 respectively. We only should check the assumption 9. By the Remark 3, $T < \frac{25C^2n^2R^n}{\sigma}$. Hence,

$$\begin{aligned} \delta = \sqrt{\varepsilon} &= \exp\left(-\frac{150C^2n^2R^n(R+2)^n}{\sigma}\right) = \\ &= \exp\left(-6(R+2)^n\frac{25C^2n^2R^n}{\sigma}\right) \leq e^{-LT}, \end{aligned}$$

that proves the Lemma. $\square$

5. FINAL ESTIMATE

Theorem 4. *The number $L(n, C, a_1, R)$ of limit cycles of (1) in the case when n is even, $C \geq 4$ and $0 < |a_1| < 2$, admits the following upper bound:*

$$L(n, C, a_1, R) < \exp\left(\exp\left(\frac{38400C^4n^2R^{n+1}(R+2)^{n+1}}{|a_1|^3(2-|a_1|)^2}e^{\frac{16\pi}{2-|a_1|}}\right)\right).$$

Proof. Now we can apply the Theorem 2. By definition, $|D|$ and $|D'|$ are less than R . The Lemma 6 provides us with the lower bound on ε . So estimates (3) and (7) imply:

$$\begin{aligned} L(n, C, a_1, R) &< \exp\left(2R \exp\left(\frac{300C^2n^2R^n(R+2)^n}{\sigma}\right)\right) \frac{R+2}{|a_1|\sigma} < \\ &< \exp\left(\frac{2R(R+2)}{|a_1|\sigma} \exp\left(\frac{300C^2n^2R^n(R+2)^n}{\sigma}\right)\right) < \\ &< \exp\left(\exp\left(\frac{600C^2n^2R^{n+1}(R+2)^{n+1}}{|a_1|\sigma^2}\right)\right) = \\ &= \exp\left(\exp\left(\frac{38400C^4n^2R^{n+1}(R+2)^{n+1}}{|a_1|^3(2-|a_1|)^2} \exp\left(\frac{16\pi}{2-|a_1|}\right)\right)\right). \end{aligned}$$

This calculation completes the proof of the Theorem. $\square$
